Notes

Functions

- ▶ A `function` is a named block of code that can be passed arguments and returns a value to the caller
- ▶ We can declare a function by writing a `declarator` of the form `f(args)`, where `f` is the name being introduced and `args` is the parameter list, for example:
 - ▶ `double mult2(double d);`
 - ▶ Note: the `base` type specifies the `return` type of the `function`
- ▶ We can define a function by including the declaration with the definition provided in `{ }` directly following the parameter list (like a compound statement, we don't have a terminating semi-colon)
 - ▶ `double mult2(double d) { return d*2; }`

Notes

Functions

- ▶ We will get into more details about `functions` later, but its helpful to understand them as they help motivate the necessity of `exceptions`

Notes

Errors

- ▶ When we write programs, errors are natural and unavoidable; the question is, how do we deal with them?
 - ▶ Organize software to minimize errors
 - ▶ Eliminate most of the errors we made anyway
 - ▶ Debugging
 - ▶ Testing

“My guess is that avoiding, finding, and correcting errors is 95% or more of the effort for serious software development.”
– Bjarne Stroustrup

Notes

Sources of errors

- ▶ Poor specification
 - ▶ “What’s this suppose to do?”
- ▶ Incomplete programs
 - ▶ “but I’ll get around to it... tomorrow...”
- ▶ Unexpected arguments to functions
 - ▶ “but `sqrt()` isn’t suppose to be called with `-1` as its argument”
- ▶ Unexpected input
 - ▶ “but the user was suppose to input an integer”
- ▶ Code that simply doesn’t do what it was supposed to do
 - ▶ “so fix it...”

Notes

Your program

- ▶ Should produce the desired results for all legal inputs
- ▶ Should give reasonable error messages for all illegal inputs
- ▶ Need not worry about misbehaving hardware
- ▶ Need not worry about misbehaving system software
- ▶ Is allowed to terminate after finding an error

Notes

Kinds of errors

Compile-time errors Errors found by the compiler

- ▶ Syntax errors
- ▶ Type errors

Link-time errors Errors found by the linker when it is trying to combine object files into an executable program

Run-time errors Errors found by checks made during a running program; that is, errors detected by

- ▶ the computer (hardware and/or the operating system)
- ▶ by a library (e.g., the standard library)
- ▶ by user code

Logic errors Errors found by the programmer looking for the causes of erroneous results

Notes

Handling non-local errors at run-time

- ▶ The caller deals with the error

```
int area1 = area(x, y);
if (area1 < 0)
```

```
    /* handle error */
```

```
else
```

```
    /* no error, continue program execution */
```

- ▶ The callee deals with errors

```
int area (int length, int width) {
    double a = length * width;
```

```
    if (a < 0)
        return 0;
```

```
    else
        return a;
```

```
}
```

Notes

How to report an error

- ▶ Return an “error value” (not general, problematic)

```
int area(int length, int width)
{
    if(length<=0 || width<=0) return -1;
    return length*width;
}
```
- ▶ So, “let the caller beware”

```
int z = area(x,y);
if (z<0) return error("`bad area'");
//...
```
- ▶ Problems:
 - ▶ What if I forget to check the value returned?
 - ▶ For some functions, there isn't a “bad value”

Notes

How to report an error

- ▶ Set an error status indicator (not general, problematic, don't)

```
int errno = 0;
int area(int length, int width)
{
    if(length<=0 || width<=0) errno = 7;
    return length*width;
}
```
- ▶ So, “let the caller check”

```
int z = area(x,y);
if (errno==7) return error("`bad area'");
//...
```
- ▶ Problems:
 - ▶ What if I forget to check `errno`?
 - ▶ How do I pick a value for `errno` that's different from all others?
 - ▶ How do I deal with that error?

Notes

How to report an error

- ▶ The previous means of error reporting are not general...
- ▶ Consider that, most of the time we can't change a function that handles errors in a way we don't like...
 - ▶ The author of the `std::vector` can detect run-time errors; however, he/she has no idea what the user would like to do about them
 - ▶ The user of the `std::vector` knows how to cope with such errors; however, he/she cannot detect them (otherwise he/she would find them in his/her own code; not left for the library to find)
- ▶ So we need a means of reporting errors in a general way...

Notes

Exceptions

- ▶ Exceptions are C++'s means of separating error reporting from error handling in a general way
 - ▶ Just about every kind of error can be reported using exceptions
 - ▶ Moreover, you can't forget about an exception: the program will terminate if someone doesn't handle it...
- ▶ You still have to figure out what to do about an exception (every exception thrown in your program)

Notes

Exceptions : Example 1

Notes

```
#include <iostream>
#include <stdexcept>
#include <limits>
using namespace std;

char to_char(int i) {
    return static_cast<char>(i);
}

int main () {
    cout << to_char(97) << endl;
    cout << to_char(155) << endl;
    return 0;
}
```

Desktop/LX_Errors-Exceptions/code
% g6 ExceptionEx1.cpp

Desktop/LX_Errors-Exceptions/code
% ./a.out
a
✚

Exceptions : Throw, Try and Catch

Notes

```
char to_char(int i) {
    if (i < numeric_limits<char>::min() || numeric_limits<char>::max() < i) {
        const string s = to_string(i);
        throw runtime_error("int" + s + " is not within the range of char");
    }
    // we get here if and only if an exception is not thrown
    return static_cast<char>(i);
}
```

- When an unexpected condition happens, we can **throw** an exception
 - **to_char** will either return the corresponding *char* of the numeric value **i**
 - or it will throw a **runtime_error**

Exceptions : Example 1b

Notes

```
#include <iostream>
#include <string>
#include <stdexcept>
#include <limits>
using namespace std;

char to_char(int i) {
    if (i < numeric_limits<char>::min() || numeric_limits<char>::max() < i) {
        const string s = to_string(i);
        throw runtime_error("int" + s + " is not within the range of char");
    }
    // we get here if and only if an exception is not thrown
    return static_cast<char>(i);
}

int main () {
    cout << to_char(97) << endl;
    cout << to_char(128);
    return 0;
}
```

Desktop/LX_Errors-Exceptions/code
% g6 ExceptionEx1b.cpp

Desktop/LX_Errors-Exceptions/code
% ./a.out
a
terminate called after throwing an instance of 'std::runtime_error'
what(): int 128 is not within the range of char
[1] 58995 abort ./a.out

Exceptions : Throw, Try and Catch

- ▶ In order to handle the problem, we must indicate that we are willing to **catch** the exception of the type used to report the problem
- ▶ If we do not catch the exception anywhere, the program will terminate (as seen in the previous example)
- ▶ Therefore, we introduce a try-block around the code where an exception might occur

```
try {  
    cout << to_char(97) << endl;  
    cout << to_char(128);  
}
```

- ▶ The try-block is followed by the *exception handler*, which specifies the type of objects that it can catch

```
catch (const runtime_error& e) { // exception handler  
    cerr << "Exception:␣" << e.what() << endl;  
}
```
